Matlab code for mel filter bank is an essential tool in speech processing, audio analysis, and various machine learning applications involving audio signals. Mel filter banks are used to emulate the human ear's perception of sound frequencies and are a critical component in feature extraction techniques such as Mel-Frequency Cepstral Coefficients (MFCCs). Implementing an efficient and accurate mel filter bank in MATLAB allows researchers and developers to process audio signals effectively, facilitating tasks like speech recognition, speaker identification, and acoustic scene analysis. In this comprehensive guide, we will explore the fundamentals of mel filter banks, their implementation in MATLAB, and provide a detailed example of MATLAB code to generate and apply a mel filter bank.

Understanding Mel Filter Bank

What is a Mel Filter Bank?

A mel filter bank consists of a series of bandpass filters spaced according to the mel scale, which approximates human auditory perception. Unlike linear frequency spacing, the mel scale is non-linear, emphasizing lower frequencies where the human ear is more sensitive.

Key points:

- Transforms the frequency spectrum into perceptually meaningful features.
- Contains overlapping triangular filters across a specified frequency range.
- Used to convert spectral data into mel-frequency domain features.

Why Use a Mel Filter Bank?

Applying a mel filter bank to an audio signal's spectral representation offers several benefits:

- Reduces the dimensionality of spectral data.
- Enhances features aligned with human hearing.
- Improves performance of speech and audio recognition systems.
- Increases robustness to noise and variations in speech signals.

Mathematical Foundations

The mel scale relates linear frequency (f) in Hertz to the mel frequency (m) as:

[

$$m = 2595 \times \log_{10}\left(1 + \frac{f}{700}\right)$$

]

Conversely, to convert mel to Hz:

[

$$f = 700 \times (10^{\frac{m}{2595}} - 1)$$

]

In designing mel filter banks:

- Define the number of filters (e.g., 26).
- Determine the minimum and maximum frequencies.
- Convert these frequencies to mel scale.
- Create equally spaced points in the mel scale.
- Convert mel points back to Hz.
- Generate triangular filters based on these points.

Implementing Mel Filter Bank in MATLAB

Steps to Generate a Mel Filter Bank

The process involves the following steps:

- Set parameters: sample rate, FFT size, number of filters, frequency range.
- Compute mel points for filter edges.
- Convert mel points to Hz.
- Map Hz points to FFT bin numbers.
- Create triangular filters based on these bins.
- Apply filters to spectral data to extract mel energies.

Key MATLAB Functions Used

- linspace: Creates linearly spaced vectors.
- fft: Computes the Fast Fourier Transform.
- zeros: Initializes filter bank matrix.
- Vector operations: Used extensively for efficient computation.

Explanation of the MATLAB Code

Parameter Initialization

The code begins by defining key parameters:

- **fs**: The sampling frequency of the audio signal, commonly 16 kHz for speech.
- **nfft**: The size of FFT, typically a power of two for efficiency.
- **numFilters**: Number of mel filters to generate, influencing the resolution.
- **lowFreq** and **highFreq**: The frequency range covered by the filter bank.

Conversion Functions

Two helper functions are used:

- **hz2mel**: Converts frequency in Hz to mel scale.
- **mel2hz**: Converts mel scale back to Hz.

These functions are based on the mathematical relations provided earlier.

Mel Points Calculation

The code computes equally spaced points in the mel scale, including the start and end points, to create the filter edges.

Mapping to FFT Bins

Converting the mel points to Hz and then to FFT bin numbers aligns the filter edges with the spectral data obtained from the FFT.

Creating Triangular Filters

The for-loop constructs each filter:

- The first loop ramps up from 0 to 1 between the start and middle bin.
- The second loop ramps down from 1 to 0 from middle to end bin.

This creates a set of overlapping triangular filters covering the spectrum.

Visualization

Plotting the filter bank helps verify the correctness of the filter shapes and spacing.

Applying the Mel Filter Bank to Audio Data

Once the filter bank is generated, it can be applied to the magnitude spectrum of an audio signal:

- Read an audio file using `audioread`.
- Pre-emphasize the audio signal to boost high frequencies.
- Divide the signal into overlapping frames.
- Compute the FFT of each frame.
- Calculate the magnitude spectrum.
- Multiply the spectrum by the filter bank matrix to obtain mel energies.
- Take the logarithm of the mel energies for further processing (e.g., MFCC extraction).

Example code snippet:

```
```matlab

% Read audio

[audio, fs] = audioread('audio_sample.wav');

% Frame parameters

frameLength = 400; % 25ms at 16kHz

overlapLength = 240; % 15ms overlap

frames = buffer(audio, frameLength, overlapLength, 'nodelay');

% Initialize matrix for mel energies

numFrames = size(frames, 2);
```

```
melEnergies = zeros(numFilters, numFrames);

for i = 1:numFrames

 frame = frames(:, i) . hamming(frameLength);

 spectrum = abs(fft(frame, nfft));

 spectrum = spectrum(1:nfft/2+1);

 melEnergies(:, i) = log(filterBank spectrum);

end

...
```

## Best Practices and Optimization Tips

- Choose an appropriate number of filters based on your application; typical values range from 20 to 40.
- Ensure the FFT size is large enough to capture the spectral details but not too large to cause unnecessary computation.
- Apply a window function like Hamming or Hann to each frame to reduce spectral leakage.
- Normalize the filter bank if necessary, especially when comparing across different datasets.
- Use vectorized operations in MATLAB for efficiency, especially when processing large datasets.

## Extensions and Advanced

**Matlab code for Mel Filter Bank** has become an essential cornerstone in the realm of speech processing, audio analysis, and machine learning applications involving sound recognition. As the demand for more accurate and efficient feature extraction methods grows, the Mel filter bank stands out as a vital component in transforming raw audio signals into meaningful representations. This article aims to delve deeply into the principles behind Mel filter banks, their implementation in Matlab, and their significance in modern audio processing pipelines.

## Understanding the Mel Scale and Its Significance

### The Human Ear and Perception of Sound

The foundation of the Mel filter bank lies in understanding how humans perceive sound frequencies.

Our auditory system does not perceive pitch linearly; instead, it perceives differences in pitch more acutely at lower frequencies than at higher ones. This perceptual characteristic is crucial for speech and audio processing as it aligns the analysis more closely with human hearing.

## What is the Mel Scale?

The Mel scale is a perceptual scale that maps actual frequency (in Hertz) to a scale that approximates human auditory perception. The scale is approximately linear up to around 1000 Hz and logarithmic thereafter, reflecting the decreasing sensitivity of human hearing with increasing frequency.

Mathematically, the Mel scale is often represented as:

$$m = 2595 \times \log_{10} \left( 1 + \frac{f}{700} \right)$$

where:

- $f$  is the frequency in Hz
- $m$  is the Mel frequency

This transformation ensures that the filter bank emphasizes frequency bands that are more perceptually relevant, making features like Mel-frequency cepstral coefficients (MFCCs) more robust and meaningful.

## Principles of Mel Filter Bank Design

### Filter Bank Construction

A Mel filter bank consists of a series of overlapping triangular filters spaced on the Mel scale. Each filter emphasizes a specific frequency band, with the entire bank covering the spectrum of interest, typically from 0 Hz up to half the sampling rate (the Nyquist frequency).

The construction involves:

- Converting the desired frequency range into Mel scale

- Creating equally spaced points on the Mel scale
- Converting these points back to Hz to determine the filter edges
- Designing triangular filters that peak at these points and overlap with neighboring filters

## Why Use Triangular Filters?

Triangular filters are computationally efficient and provide a smooth transition between adjacent frequency bands. They are designed such that:

- Each filter rises linearly from zero at its lower edge to a peak at its center frequency
- Then falls back linearly to zero at its upper edge

This shape ensures that the sum of all filters covers the entire spectrum without gaps or overlaps that could distort the feature extraction process.

## Implementing Mel Filter Bank in Matlab

### Step-by-Step Approach

Implementing a Mel filter bank in Matlab involves several key steps, each critical for accurate and efficient feature extraction.

- Parameter Initialization
  - Sampling frequency ( $F_s$ )
  - Number of filters ( $\text{numFilters}$ )
  - FFT size ( $N_{\text{FFT}}$ )
  - Frequency range (usually from 0 to  $F_s/2$ )
- Compute Mel-Spaced Points
  - Convert the frequency range from Hz to Mel scale
  - Generate equally spaced points in Mel scale
  - Convert Mel points back to Hz

- Determine Filter Edges
- Map Mel points to FFT bin numbers
- Define the triangular filters based on these bin indices
- Construct Filter Bank Matrix
- For each filter, assign weights to the FFT bins based on the triangular shape
- Store these in a matrix where each row corresponds to a filter
- Apply Filter Bank to Power Spectrum
- Compute the power spectrum of the signal
- Multiply the spectrum by the filter bank matrix
- Sum the energy within each filter to obtain filter bank energies

Sample Matlab Code Snippet:

```
```matlab

function filterBank = melFilterBank(Fs, NFFT, numFilters)

% Convert frequency range to Mel scale

fMin = 0;

fMax = Fs/2;

melMin = hz2mel(fMin);

melMax = hz2mel(fMax);

% Generate Mel points

melPoints = linspace(melMin, melMax, numFilters + 2);
```

```
hzPoints = mel2hz(melPoints);

% Convert Hz to FFT bin numbers

bin = floor((NFFT + 1) hzPoints / Fs);

filterBank = zeros(numFilters, floor(NFFT/2 + 1));

for m = 1:numFilters

    f_m_minus = bin(m);

    f_m = bin(m + 1);

    f_m_plus = bin(m + 2);

    % Create triangular filters

    for k = f_m_minus:f_m

        filterBank(m, k + 1) = (k - f_m_minus) / (f_m - f_m_minus);

    end

    for k = f_m:f_m_plus

        filterBank(m, k + 1) = (f_m_plus - k) / (f_m_plus - f_m);

    end

end

end

end

function mel = hz2mel(hz)

    mel = 2595 log10(1 + hz / 700);

end

function hz = mel2hz(mel)
```

```
hz = 700 (10.^(mel / 2595) - 1);
```

```
end
```

```
...
```
